ADHOC – MAC : a new, flexible and reliable MAC architecture for ad-hoc networks

F. Borgonovo, A. Capone, M. Cesana, L. Fratta

***Dipartimento Elettronica e Informazione
Politecnico di Milano***

Ad-Hoc Networks

- ☐ No fixed infrastructure
- ☐ Limited propagation range
- ☐ Need for terminal relaying/routing

Inter-vehicles ad-hoc Networks

□ Application scenarios:

- Self sustaining networks
- No need of central control
- High Flexibility
- Effective MAC
- Robust Physical Level

- Traffic control
- Entertainment
- Internet access
- Extension to backbone services

MAC problem: Hidden terminal

not completely solved by IEEE 802.11 (CSMA/CA)

Impact on :

- radio access
- local broadcast

MAC problems: exposed terminal

unsolved by IEEE 802.11 (RQS/CLS)

Impact on efficiency since parallel transmissions can be prevented

MAC problems: broadcast service

how to choose bridges

Tree-based protocols not applicable due to dynamic topology

Flooding highly inefficient with high degree of connectivity (n transmissions instead of 1)

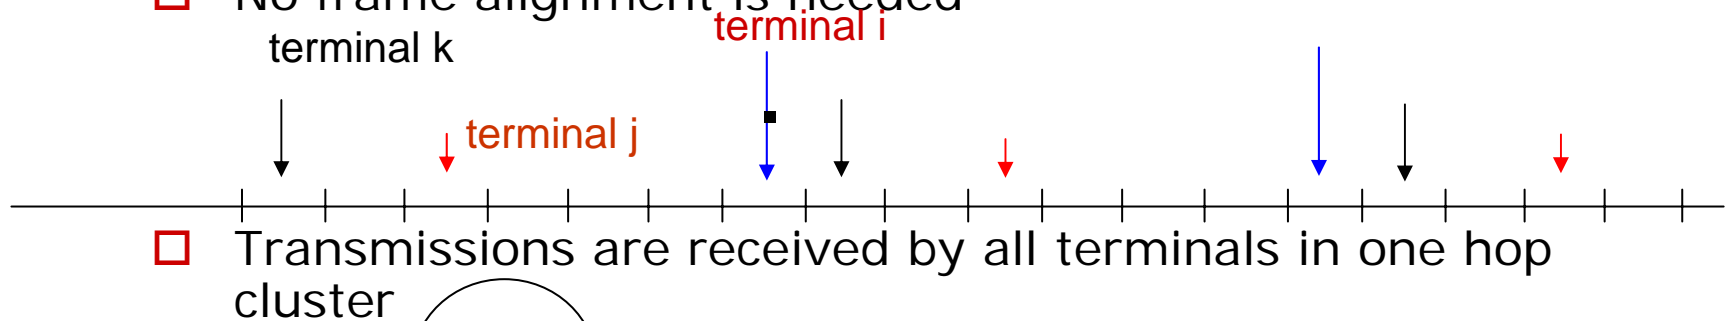

□ Features:

- Layer two connectivity information
- Access to a reliable single-hop broadcast
- QoS support for different applications
- Efficient point-to-point communication (parallel transmissions)
- Efficient multi-hop broadcast

ADHOC MAC

- Time slotted channel
- By external sources (GPS)
 - By first active terminal
- Basic Channel (BCH)
 - All active terminals periodically transmit channel status information
 - Slots are grouped into virtual frames (VF) of length N
 - No frame alignment is needed

BCH is established by the
Reliable Reservation ALOHA protocol

Reservation ALOHA

a distributed way to establish TDMA channels

a slot successfully captured is periodically reserved (every N slots) till released

Reservation ALOHA

needs a centralized radio environment (full broadcast)
so that all terminals “see” the same slot status:
busy, free, collided

Reliable Reservation ALOHA

- operates in a distributed radio environment with limited broadcast capability (hidden terminals, interference, no ACK)
- each terminal propagates slot status information (Frame Information) using BCH

Reliable Reservation ALOHA

- all active terminals transmit the **Frame Information** every N slots (frame)
- FI specifies the status of the previous N slots (Sliding Virtual Frame) as observed by the terminal
 - BUSY correct transmission
 - FREE no transmission or collision

RR-ALOHA : Frame Information

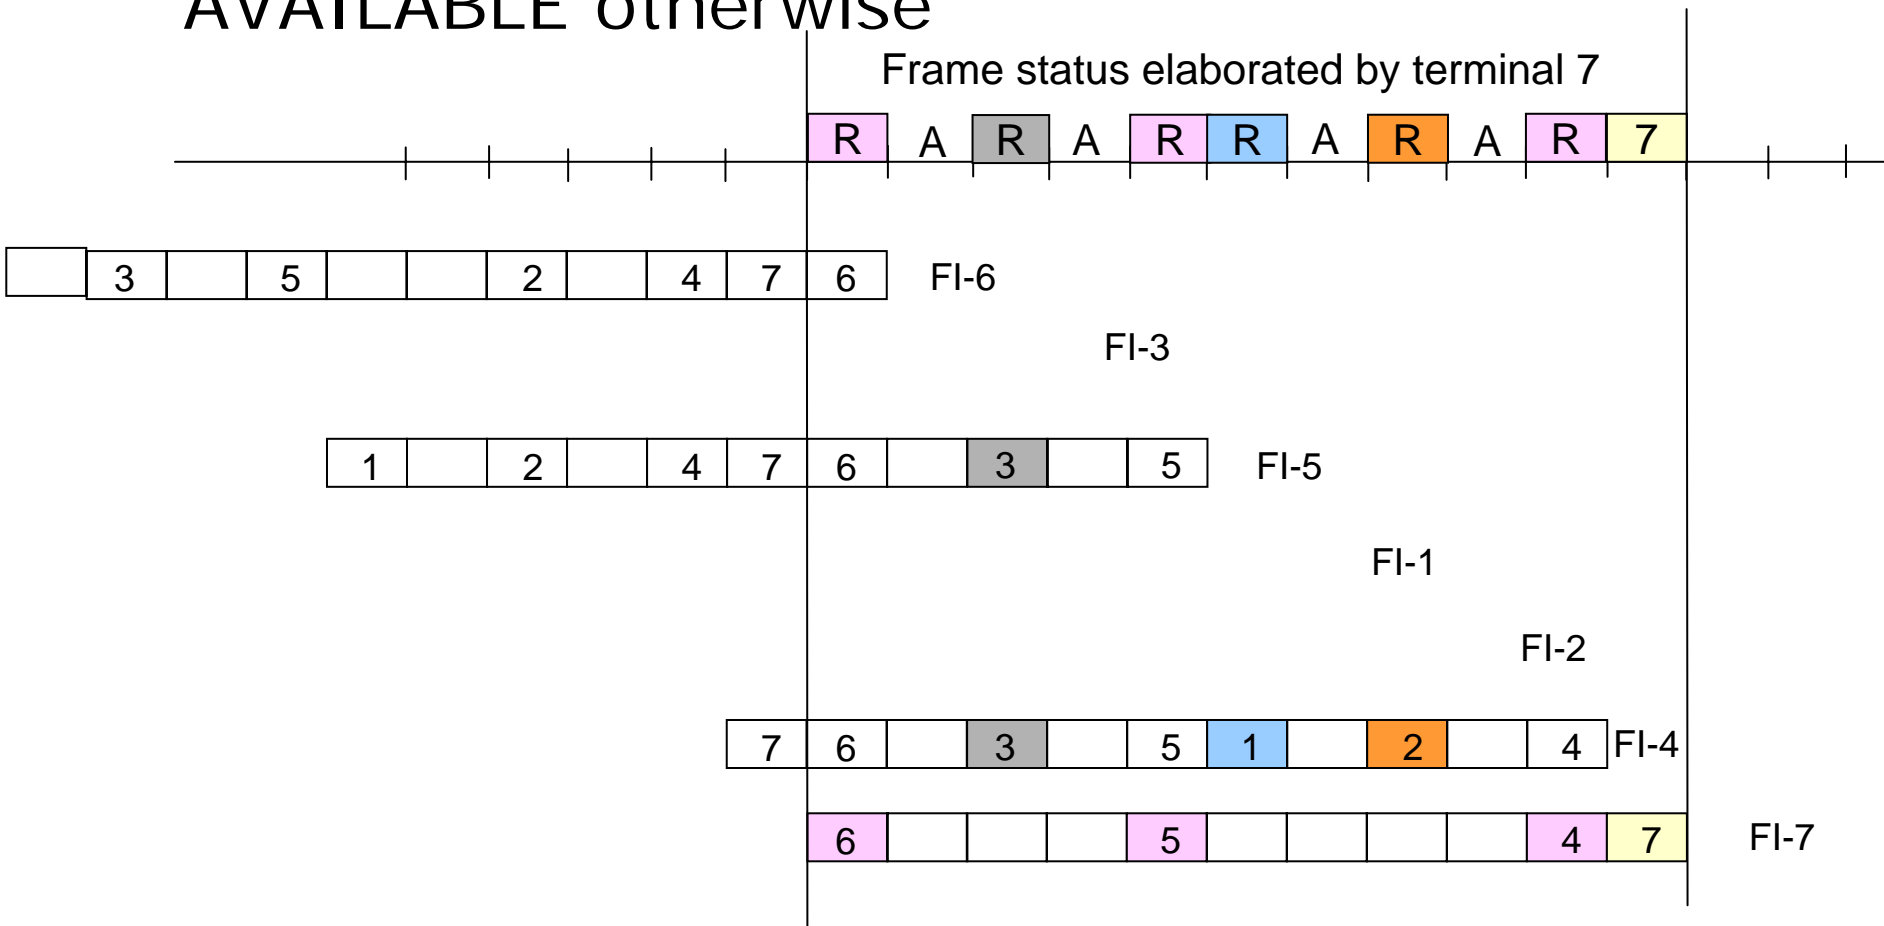

Transmissions

RR-ALOHA : slot status

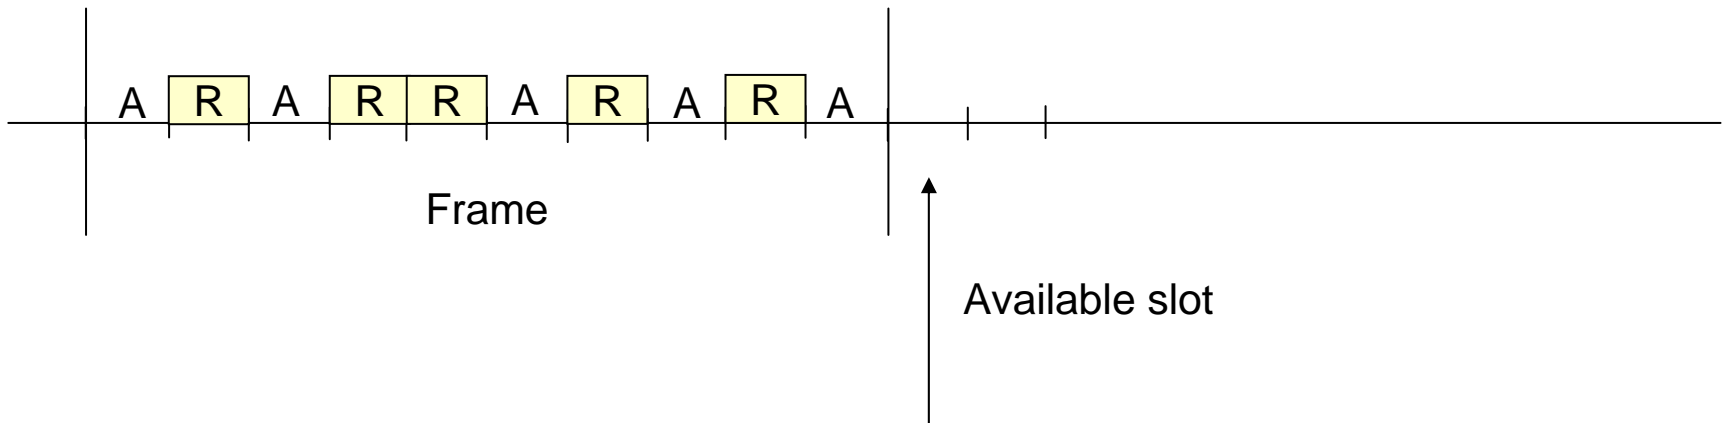

RESERVED if at least one FI says "BUSY"
AVAILABLE otherwise

RR-ALOHA : access

- ❑ AVAILABLE slots can be used:
 - ❑ by a new active terminal (as in R-ALOHA)
 - ❑ by an already active terminal to increase its transmission bandwidth
- ❑ No Hidden-Terminal problem

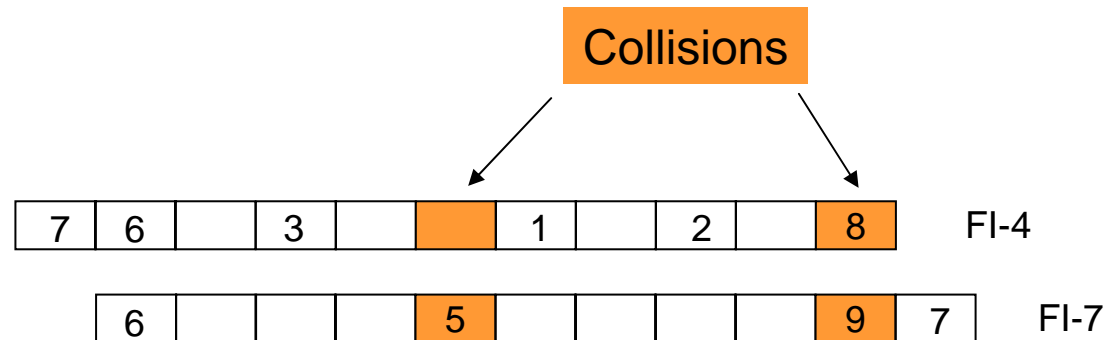

RR-ALOHA : access

The ID of the slot “owner” must be included in the FI

The transmission is successful if

- ❑ the slot is coded as BUSY with the same station ID in all the received FI

RR-ALOHA : access

One terminal
attempting access:

- All terminals in the same cluster recognize the transmission.
- All FI will code the slot as BUSY.
- All other terminals will receive FI with the slot as BUSY.
- The slot is declared RESERVED.

More terminals
attempting access:

- The terminal recognizing collision codes the slot as FREE.
- The slot remains AVAILABLE.

RR ALOHA : common frame

- a unique frame is established among non disjoint radio broadcast domains based on FIs transmitted by nodes in common

RR ALOHA : slot reuse

23 transmissions in 13 slots

Reserving additional bandwidth

- ❑ Each active station sets up and manages a BCH
- ❑ Payload can be transmitted in the BCH slots
- ❑ Additional available slots can be reserved for increasing transmission bandwidth (**additional channels**)

Reserving additional bandwidth

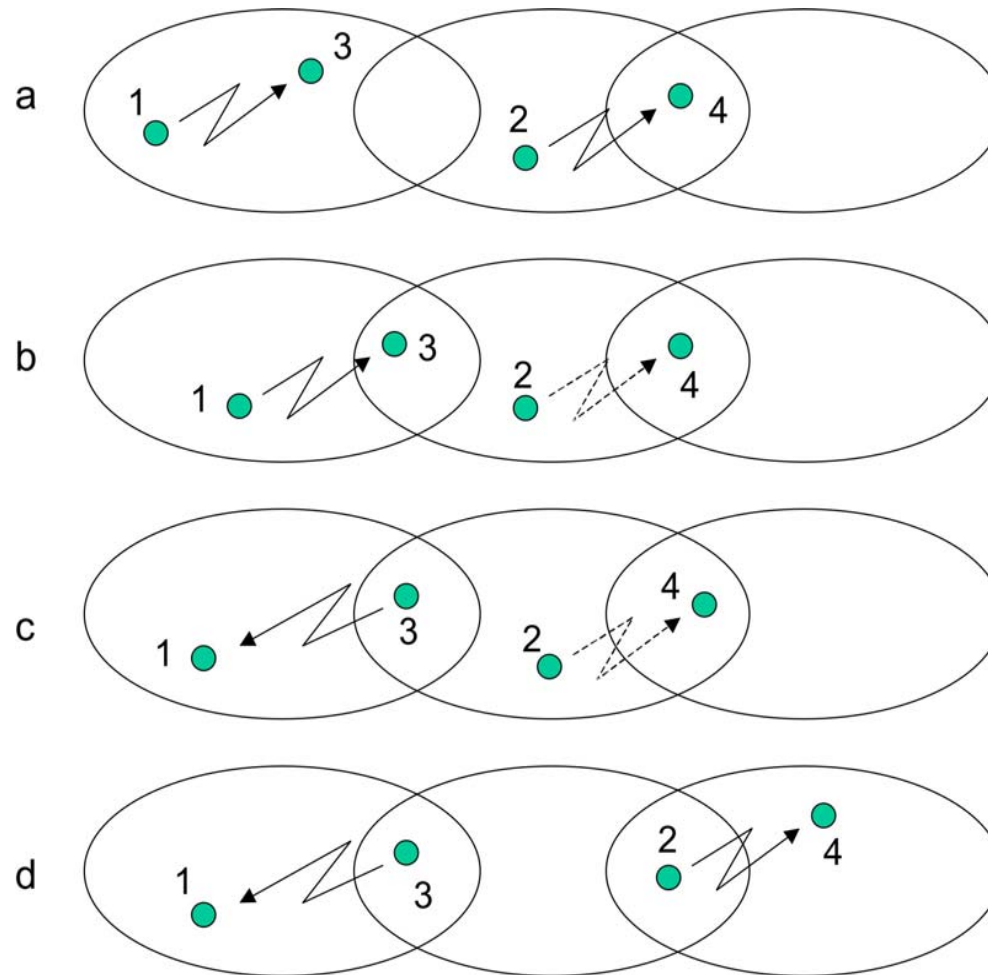

- ☐ Using RR- ALOHA procedure on the AVAILABLE Slots
- ☐ Using established BCH.
 - ☐ New channel requests are signaled
 - ☐ Possibility of priority management
 - ☐ FI guarantees reservation collision detection

ADHOC MAC : Point-to-point channels

- ❑ To exploit slot reuse in the same or adjacent clusters (parallel transmissions)
- ❑ PTP flag is needed in the FI for each slot
- ❑ PTP flag is set by a terminal if:
 - The packet received is broadcast or
 - The packet is destined to the terminal itself
- ❑ A reserved slot can be accessed if:
 - The PTP flag is off in all received FI and
 - The FI received from the intended destination marks the slot FREE
- ❑ Due to concurrent access attempts: the transmission is successful if the slot is coded as BUSY in the FI of the destination terminal.

ADHOC MAC : Point-to-point channels

ADHOC MAC : Multi-hop Broadcast service

C_i the set of neighbors of i
 $S_i \subseteq C_i$ the subset of neighbors
that have not received
the broadcast packet in slot k

} from FIs

Terminal i relays the broadcast packet received in slot k if

$$|S_i| > 0$$

and the following condition is **not** satisfied for all j

$$S_i \subseteq C_j \text{ AND } \left\{ |C_j| > |C_i| \text{ OR } \left\{ |C_j| = |C_i| \text{ AND } ID_j > ID_i \right\} \right\}$$

Multi-hop Broadcast mechanism

One terminal for each set AB, BC and CD is elected as relay terminal

Simulation Analysis

- ☐ Fixed Radius (r parametric)
- ☐ Uniform Power
- ☐ 1Km^2 Square Area
- ☐ Poisson distributed users (G parametric)

Access Delay

$r = 1000 \text{ m}$

$r = 100 \text{ m}$

- Very prompt access
- With slot reuse the access delay is even lowered

Single Hop Broadcast Performance

THROUGHPUT LIMITING FACTORS

- Collisions due to access and clusters' fusion
- Spatial reuse

Throughput Limiting Factors

ACCESS

■ **COLLISIONS**

CLUSTERS' FUSION

BEFORE

AFTER

■ **SPATIAL REUSE**

Collisions

ACCESS COLLISIONS

FUSION COLLISIONS

Spatial Reuse

Not all the slots within a OH cluster can be used for internal transmissions

The hidden terminal problem is solved but spatial reuse is lowered

Broadcast Multi Hop

- Flooding
- ADHOC MAC
- Centralized Greedy

For high connected topologies
ADHOC spares 80% of
relaying transmissions with
respect to flooding

Conclusions

PROs

- Suitable for highly variable ad-hoc net environment
- Fast access to a reliable single-hop broadcast
- Provision of different QoS according to applications needs
- Parallel transmissions for point-to-point communications
- Efficient multi-hop broadcast

CONs

- High overhead (25%)
- Power saving is jeopardized by the need for the BCH
